CHAPTER 12
Distributing TensorFlow Across Devices and Servers

In Chapter 11 we discussed several techniques that can considerably speed up training: better weight initialization, Batch Normalization, sophisticated optimizers, and so on. However, even with all of these techniques, training a large neural network on a single machine with a single CPU can take days or even weeks.

In this chapter we will see how to use TensorFlow to distribute computations across multiple devices (CPUs and GPUs) and run them in parallel (see Figure 12-1). First we will distribute computations across multiple devices on just one machine, then on multiple devices across multiple machines.

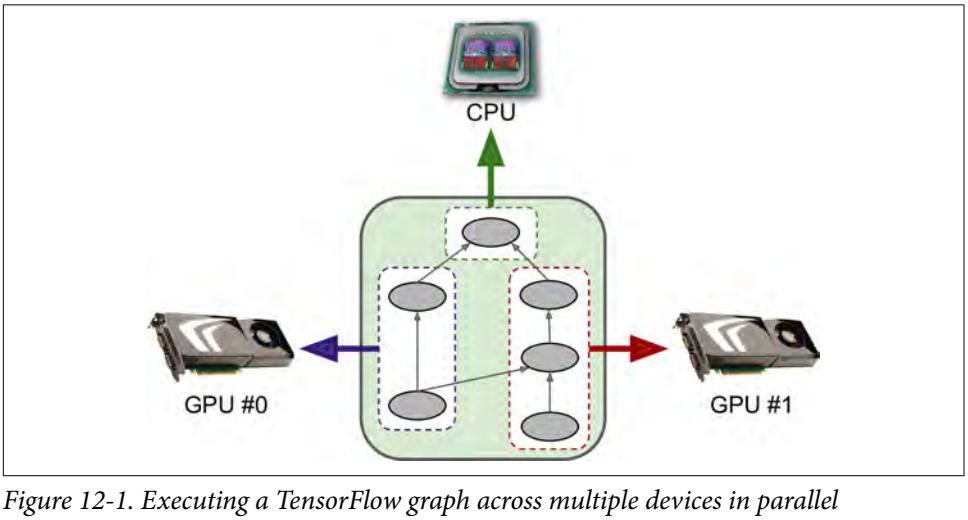

Figure 12-1. Executing a TensorFlow graph across multiple devices in parallel

TensorFlow's support of distributed computing is one of its main highlights compared to other neural network frameworks. It gives you full control over how to split (or replicate) your computation graph across devices and servers, and it lets you parallelize and synchronize operations in flexible ways so you can choose between all sorts of parallelization approaches.

We will look at some of the most popular approaches to parallelizing the execution and training of a neural network. Instead of waiting for weeks for a training algorithm to complete, you may end up waiting for just a few hours. Not only does this save an enormous amount of time, it also means that you can experiment with various models much more easily, and frequently retrain your models on fresh data.

Other great use cases of parallelization include exploring a much larger hyperparameter space when fine-tuning your model, and running large ensembles of neural networks efficiently.

But we must learn to walk before we can run. Let's start by parallelizing simple graphs across several GPUs on a single machine.

Multiple Devices on a Single Machine

You can often get a major performance boost simply by adding GPU cards to a single machine. In fact, in many cases this will suffice; you won't need to use multiple machines at all. For example, you can typically train a neural network just as fast using 8 GPUs on a single machine rather than 16 GPUs across multiple machines (due to the extra delay imposed by network communications in a multimachine setup).

In this section we will look at how to set up your environment so that TensorFlow can use multiple GPU cards on one machine. Then we will look at how you can distribute operations across available devices and execute them in parallel.

Installation

In order to run TensorFlow on multiple GPU cards, you first need to make sure your GPU cards have NVidia Compute Capability (greater or equal to 3.0). This includes Nvidia's Titan, Titan X, K20, and K40 cards (if you own another card, you can check its compatibility at *https://developer.nvidia.com/cuda-gpus*).
